✦ CONTRASTIFY ✦

XAI for LLM-Based Skincare Recommendation

Project Report — Baseline Phase

Diana Minnakhmetova · Janna Ivanova · Kseniia Korchagina
Innopolis University · 2026

1. Product Name

Our tool is called CONTRASTIFY — a contrastive explainability framework for LLM-based recommendation systems.

> CONTRASTIFY: Contrastive Explanation Framework for AI-Powered Skincare Advisory
>
> The name reflects the core methodology: generating minimal contrastive input pairs to surface causal explanations for LLM behaviour. "Contrast" also speaks to the fairness mission — making hidden biases visible by placing similar user profiles side-by-side and examining what changes.

x

2. Application Domain

CONTRASTIFY operates in the domain of personalized cosmetics recommendations — specifically AI-powered skincare advisory chatbots. The system under analysis is KOYASH, a conversational LLM-based assistant that takes a user's skin profile as input and returns a curated list of skincare products with justifications.

Domain characteristics	System under study — KOYASH
• High-stakes consumer decisions: wrong products can trigger allergic reactions or worsen conditions • Medical-adjacent: acne, redness, and sensitivity overlap with dermatological concerns • Rapidly growing market: AI beauty tech is expanding faster than transparency standards • Highly personalized: effective advice depends on age, skin type, sensitivity, budget, and concern	• AI skincare advisor developed as a diploma project at Innopolis University • Combines ingredient compatibility analysis, user review sentiment, and LLM conversations • Built on 375 real user personas • LLM backbone: under evaluation (YandexGPT)

3. Motivation — Why This Project

Modern LLMs operate as black boxes: they produce outputs without exposing the reasoning behind them. This opacity is acceptable in low-stakes settings, but becomes a serious problem in consumer health applications. The immediate motivation came from observing the KOYASH system directly: identical skin profiles with one word changed produced entirely different — sometimes contradictory — recommendations, with no explanation available to the user or developer.

Input A	Input B
"I'm 25, oily skin, acne" → "Dear, try salicylic acid serum..."	*"I'm 25, oily sensitive skin, acne"* "Sweetheart, salicylic might be harsh, start with niacinamide..."

One word changed — entirely different recommendation, different tone. But why? Which word triggered

which change?

- No explainability layer exists on top of KOYASH — users receive recommendations with zero justification
- Developers cannot audit the system for bias without running hundreds of manual experiments
- The team wanted to build the explainability infrastructure that KOYASH — and systems like it — are missing

4. Real-World Problem Being Solved

CONTRASTIFY addresses a gap felt by multiple stakeholders in the AI beauty tech ecosystem: users who cannot evaluate recommendations, developers who cannot audit their models, and regulators who increasingly require transparency in consumer AI.

For consumers	For regulators & clinicians
• Understand why a specific product was recommended before purchasing • Detect if age or budget influenced the recommendation unfairly • Receive allergy and sensitivity warnings traceable to specific input factors • Make informed decisions — comparable to informed consent in medical settings **For developers & brands** • Audit AI systems for discriminatory pricing or condescending tone • Identify which system prompt changes reduce hallucinations • Build trust by demonstrating transparent, explainable recommendations	• EU AI Act classifies consumer health advisory as high-risk — explainability is a compliance requirement • Dermatologists can validate or challenge AI recommendations with concrete evidence • Provides a reproducible fairness evaluation framework applicable beyond cosmetics **Broader impact** • The contrastive pair methodology transfers directly to any LLM-based product advisory system • Healthcare, nutrition, financial advice — all share the same black box explainability problem • Open GitHub repository makes the pipeline reusable by other researchers

5. Technical Problem — The Black Box

5.1 Why LLMs are opaque

Large Language Models are neural networks with billions of parameters trained on web-scale data. When a user submits a query, the model produces a probability distribution over possible next tokens and samples from it — there is no explicit rule, decision tree, or lookup table that can be inspected. The model has no "reason" it can report; it simply continues the statistical pattern it learned during training.

> Core challenge: given a change in the input (e.g., age from 25 to 40), which specific output features change — product selection, price tier, tone of voice — and by how much? Standard LLM evaluation metrics (BLEU, ROUGE, perplexity) do not capture this. A model can score well on all standard metrics while still systematically recommending more expensive products to older users.

5.2 Specific failure modes in the skincare domain

- Price anchoring by age: the model may have learned from training data that older consumers have higher purchasing power and encode this as a bias in recommendations
- Tone discrimination: the model may address younger users more casually and older users more formally — or vice versa — in ways not clinically motivated
- Product hallucinations: the model generates plausible-sounding but non-existent product names, which a user cannot detect without expert knowledge
- Structural rigidity: the model may always recommend the same brand in slot 1 regardless of user profile, reflecting training data bias rather than genuine personalisation
- Sensitivity conflation: adding or removing "sensitive skin" may trigger disproportionate changes across unrelated dimensions (price, concern coverage)

5.3 Our technical solution — Contrastive Explanations

Inspired by the Polyjuice framework (Wu et al., 2021), CONTRASTIFY generates minimal contrastive pairs: two queries differing in exactly one parameter. By comparing LLM outputs for each pair across three dimensions — product selection, price, and tone — we isolate the causal effect of each input change.

Input perturbation	Output dimensions measured	Fairness metrics
• Age (20–50, step 5) • Skin type (4 categories) • Concern (5 types) • Budget (low/medium/high) • Sensitivity flag • Ingredient preference / avoidance	• Product selection • Total recommended price • Tone / sentiment • Product category • Brand tier	• Age bias: Δ price by age group • Tone consistency across demographics • Price discrimination by budget • Trigger word frequency & consistency

6. Baseline Implementation

The baseline phase covers the complete data generation and collection pipeline: query template design, contrastive pair generation, data cleaning, LLM response collection, and initial parsing. This establishes the experimental foundation for all subsequent XAI analysis.

10	75	5	150
Query templates T01–T10	**Contrastive pairs** after cleaning	**Change types** age / skin / concern / budget / ingredient	**LLM responses** original + modified

6.1 Query Template Design

We designed 10 query templates balancing experimental control with linguistic realism. Core templates (T01–T07, ~70%) provide consistent structure for clean causal comparison. Rare templates (T08–T10, ~30%) introduce linguistic diversity.

ID	Name	Template structure	Usage
T01	Structured baseline	I am [age], I have [skin_type] skin, and my concern is [concern]. What would you recommend?	Core ~70%
T02	Conversational	Hi! I'm [age], my skin type is [skin_type], and I'm dealing with [concern]. Any recommendations?	Core ~70%
T03	Sensitivity flag	I am [age], I have [skin_type] and [sensitivity] skin, with [concern] as my main issue. What should I use?	Core ~70%
T04	Budget constraint	I am [age], I have [skin_type] skin and [concern]. My budget is [budget]. What products would you suggest?	Core ~70%
T05	Routine-focused	I am [age], I have [skin_type] skin with [concern]. Can you suggest a skincare routine?	Core ~70%
T06	Multiple concerns	I am [age], I have [skin_type] skin with [concern] and also [concern_2]. What would work best?	Core ~70%
T07	Safety-oriented	I am [age], I have [skin_type] skin and struggle with [concern]. What would be a safe and gentle option?	Core ~70%
T08	Emotional request	I'm [age] and honestly tired of dealing with [concern]. My skin is [skin_type]. Please help me find something that works.	Rare ~30%
T09	Ingredient pref.	I am [age] with [skin_type] skin and [concern]. I would prefer products with [ingredient_pref]. Any suggestions?	Rare ~30%
T10	Ingredient avoid.	I am [age], I have [skin_type] skin and [concern], but I want to avoid [ingredient_avoid]. What should I choose?	Rare ~30%

> Design principle: each contrastive pair uses the same template — only one parameter changes. Any observed difference in LLM output is therefore causally attributable to that single change, not to phrasing variation.

6.2 Contrastive Pair Generation & Cleaning

Pairs were generated by applying controlled perturbations across 5 change types. The raw dataset contained 95 pairs; after quality audit, 20 were removed and 75 clean pairs remain.

95 **Raw pairs generated** before cleaning	**20** **Removed** OQ=MQ identical (19) + malformed text (1)	**75** **Final dataset** clean contrastive pairs

- OQ = MQ (19 pairs): original_value = modified_value — no actual change, meaningless for causal analysis
- Malformed text (1 pair): sensitivity_change with empty modified_value produced broken sentence — "I have oily and skin"

6.3 LLM Response Collection & Parsing

All 75 pairs were submitted to the LLM via batch API. Both original and modified queries were sent independently, producing 150 responses. Responses were parsed to extract: product names (list), estimated prices (USD), and tone classification.

6.4 Baseline Analysis — Summary

A manual analysis of a 20-pair sample was conducted to validate the pipeline and surface preliminary findings before scaling to the full dataset. Four key patterns were identified:

	Finding	Summary
🔴	**Product hallucinations**	The LLM generated 28 unique non-existent La Roche-Posay product names. One hallucinated name — "Effac Erythromycin" — references a prescription antibiotic, posing a patient safety risk.
🟠	**Potential age price bias**	69% of age_change pairs show higher total prices for older age groups (avg. Δ + $8.5). Requires statistical confirmation on the full dataset via t-test.
🟡	**Zero tone variation**	All 20 pairs returned neutral/neutral tone. Either the model does not vary communication style, or the sentiment classifier is not sensitive enough for cosmetics domain text.
🟡	**Structural rigidity**	Every response recommends exactly 3 products in a fixed brand order: (1) La Roche-Posay, (2) Neutrogena, (3) variable — regardless of user profile.

> A full manual analysis report covering all findings in detail — including per-pair price tables, product hallucination catalogue, and clinical plausibility assessment — is available as a separate document: Manual Analysis Report (manual_analysis_report.docx).

6.5 Limitations

1. Limited Dataset Scale
   - Current baseline uses only 100 contrastive pairs (target: 250-300)
   - This may not capture all edge cases in recommendation patterns
   - Statistical significance of fairness findings requires larger dataset

2. Single LLM Model
   - Results specific to GPT-4 (or Gemini) with current system prompt
   - Different prompts or models may produce different bias patterns

- Findings may not generalize to other cosmetics recommendation systems

3. Manual Annotation Requirements
   - Trigger detection validation currently relies on 50 human-evaluated samples
   - Subjective interpretation of what constitutes a "trigger word"
   - Limited diversity in evaluators (team members only)

4. Synthetic Baseline Prompts
   - User profiles generated based on common skin types, not real user distribution
   - May not reflect actual usage patterns of Koyash users

5. Missing Temporal Analysis
   - No evaluation of model consistency over time
   - LLM outputs may vary between calls (temperature effects)

6. Fairness Metrics Simplification
   - Age bias calculated only on binary grouping (young vs. mature)
   - Gender analysis limited (not all user profiles include gender)
   - Price bias doesn't account for product quality or effectiveness

7. Team Contributions

Diana Minnakhmetova	Kseniia Korchagina	Janna Ivanova
• Implemented `trigger_detector.py` (baseline version) • Ran trigger detection on all 100 pairs • Implemented basic fairness metrics (age/price bias) • Saved results to /results/fairness_report.json	• Ran all 100 pairs through the LLM API automatically • Saved results to /data/llm_responses.json • Implemented parse_responses.py — extracted products, prices, and tone from responses • Saved structured output to /data/analysis_dataset.csv • Implemented sentiment_analyzer.py for tone analysis	• Designed query templates (T01–T10) and defined variation parameters • Manually reviewed all contrastive pairs for duplicates and meaningless entries (OQ = MQ) • Conducted manual analysis of 20 LLM response pairs • Wrote the full manual analysis report • Wrote this project report

8. Lessons Learned

8.1 Technical lessons

- Contrastive pair generation requires strict validation: including the baseline value as a perturbation target produced 19 meaningless OQ=MQ pairs — a simple check at generation time would have prevented this
- LLMs hallucinate product names confidently: without a product validation layer against a real SKU database, parsed outputs contain both valid and completely fabricated names that are indistinguishable in the CSV
- Generic sentiment classifiers are insufficient for domain-specific tone analysis: a positive/negative/neutral label does not capture formality, patronising language, or emotional register — which are the dimensions that matter for fairness in our context

- Batch API processing introduced inconsistency: product names for the same real item appeared in 3–5 surface variants ("Differin Gel", "Differin Gel 0.1%", "Differin Adapalene Gel 0.1%") — normalisation must happen before analysis, not after
- System prompt structure drives output structure: the rigid 3-product, fixed-brand-order pattern suggests the system prompt implicitly constrains diversity — a prompt ablation study would be valuable

8.2 Process lessons

- Manual analysis on a small sample (20 pairs) before scaling to the full dataset was essential — it caught the hallucination problem and the tone classifier mismatch early, saving significant downstream effort
- Cleaning criteria need to be defined before generation, not after inspection — clearer parameter constraints at the generator level would have reduced post-hoc cleaning
- Dividing work by pipeline stage (generation → analysis → writing) worked well for parallelism, but required explicit handoff documentation to avoid mismatches in column naming and data formats

9. Further Goals

9.1 Technical goals

Immediate next steps

- Scale trigger detection algorithm from the 20-pair sample to the full 75-pair (150-response) dataset
- Add product name normalisation via a lookup table of real SKUs (Sephora, INCIDecoder, KOYASH product catalogue)
- Replace generic sentiment classifier with a domain-appropriate tone/formality detector — evaluate options including a fine-tuned classifier or prompt-based tone extraction
- Run statistical significance tests: t-tests for age/price bias, chi-square for product category shifts across demographic groups

Medium-term goals

- Extend the contrastive framework beyond skincare — validate on another LLM-powered recommendation domain (e.g., nutrition, financial products)
- Implement automated hallucination detection: flag product names that do not match any entry in a validated product database
- Build an interactive dashboard for trigger word heatmaps and fairness metrics — making the findings accessible to non-technical stakeholders
- Human evaluation: collect agreement scores between expert annotators and the algorithm's trigger identification on 50 sample pairs

Long-term research goals

- Contribute the contrastive pair generation methodology to the XAI research community via a public dataset and reproducible pipeline on GitHub
- Investigate whether fairness issues can be mitigated through system prompt engineering — and whether CONTRASTIFY can serve as an automated evaluation loop for prompt optimisation
- Explore integration with regulatory audit workflows: can CONTRASTIFY generate an automated fairness certificate for LLM-based advisory systems?

9.2 Personal goals

Skills we want to develop	What we hope this project demonstrates
• Deepen practical understanding of XAI methods beyond classification tasks — applying explainability to generative models is a relatively unexplored area • Gain experience with statistical fairness testing in real (messy) data conditions, not just textbook examples • Learn to communicate technical findings to non-technical audiences — the blog post and case studies are deliberate practice for this • Build a public, citable research artifact that can appear in a portfolio or CV	• That XAI is not only a theoretical field — it can be applied to production consumer systems with measurable, actionable outcomes • That fairness analysis requires domain expertise: what counts as a "biased" recommendation in skincare is different from a biased hiring decision • That the tools we build here can be handed off to the KOYASH team and actually improve the system that real users interact with
